

# Wealth inequality: Britain in international perspective

---

Frank Cowell: Wealth Seminar June 2012

# Questions

- What does UK wealth inequality look like in context?
- What is role of inequality among the rich?
  - graphical overview
  - investigate comparisons of alternative “rich” definitions
  - decomposition analysis
- Sensitive to what we mean by wealth?
  - graphical overview
  - investigate comparisons of alternative wealth concepts
- Sensitive to assumptions about the upper tail?
  - semi-parametric modelling
  - reuse decomposition analysis

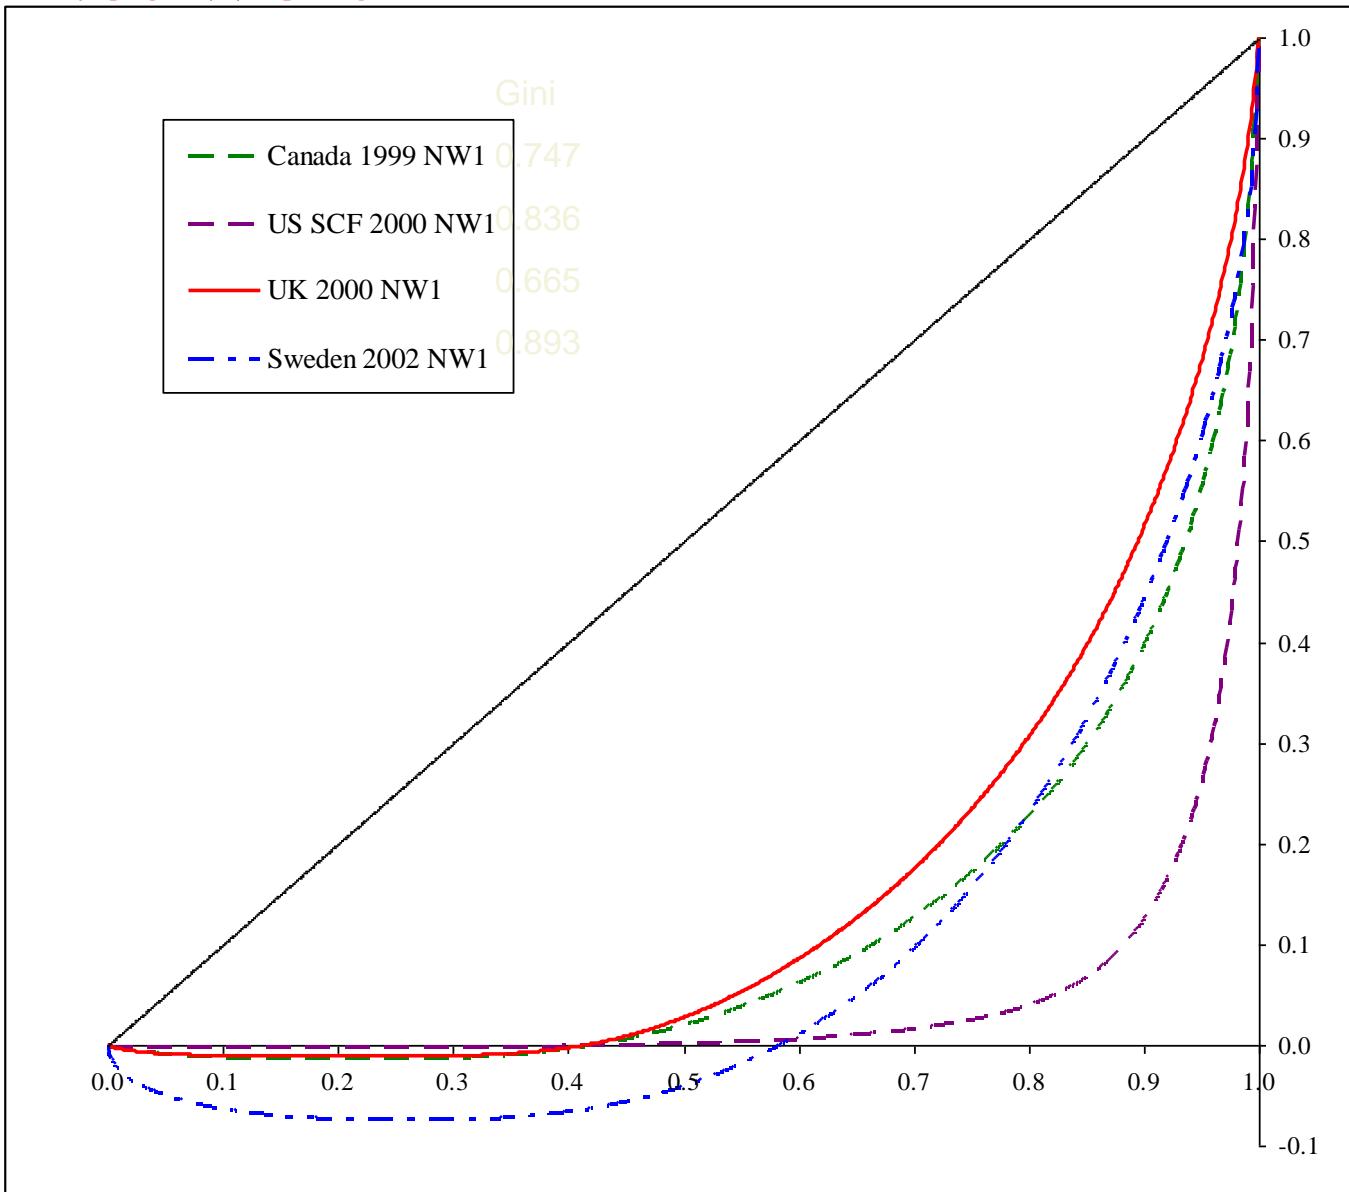

# Tools

- Use consistent definitions from LWS
- Compare with US, Canada, Sweden
  - all available with roughly the same wealth definition
  - all available around the year 2000
- Focus on Net Worth 1
  - “industry standard” for wealth comparisons
  - this version excludes business equity
- Use standard tools for description and modelling
  - Gini index
  - Pareto model

# A model for wealth distribution

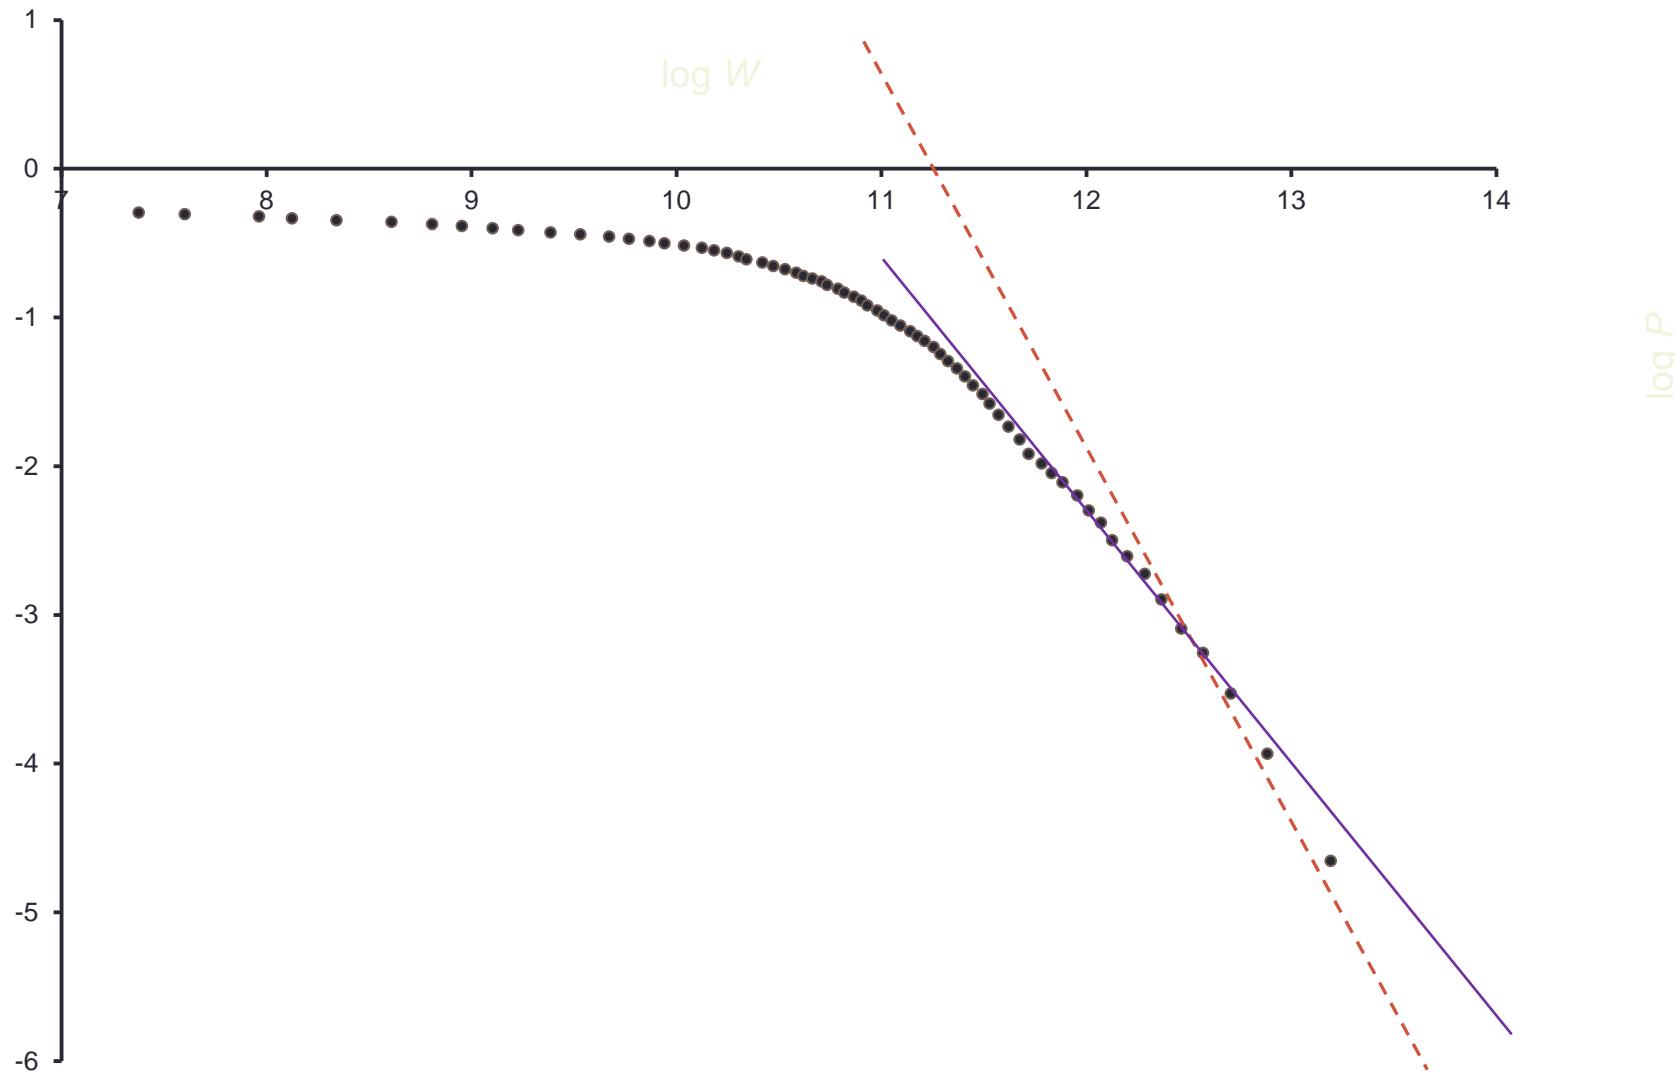

- Distinctive shape of empirical wealth distribution
- Upper tail appears to conform to Pareto model
- Pareto distribution
  - $F(x) = 1 - [\underline{x} / x]^\alpha$
  - $f(x) = \alpha \underline{x}^\alpha x^{-\alpha-1}$
- Simple interpretation
  - $\alpha$  captures “weight” of tail
  - $\underline{x}$  “locates” the distribution
- Inequality

$$\frac{a_{\text{average}}}{b_{\text{base}}} = \frac{\alpha}{\alpha - 1}$$

$$\text{Gini}^* = \frac{1}{2\alpha - 1}$$

# UK Wealth: Pareto diagram

# Modelling the rich

- A semi-parametric approach to analysing wealth distribution
- Several motives for doing this
  - patchy data
  - under-reporting?
  - inequality sensitive to outliers?
- Assume that upper tail has “Pareto” shape
  - standard in the wealth literature
  - plot proportion with wealth of at least  $x$  against  $x$
  - will be a straight line if done on a double-log graph
- Just a case of fitting a straight line?
  - standard regression may be sensitive to outliers
  - robust methods are available

# Modelling and inequality

- Two effects:
  1. the within-rich-group Gini
  2. the share of the rich group
- Econometric method will affect inequality estimates
  - simple Ordinary Least Squares
  - robust estimation (downweights outliers)
- But the effect depends on the nature of the data
  - which way does the tail “bend”?
  - does the estimated Pareto model produce a sensible answer?
- We’re remodelling the “top corner” of Lorenz curves
  - combines both effects 1 and 2

# Conclusions

- Three comparator countries
  - do they fit our preconceptions?
  - variety of wealth composition
- UK Net worth not as unequal as we might think?
- Conclusion fairly robust to choice of wealth variable
  - also true for total assets
  - but not for total financial assets
- Conclusion also robust to modelling the rich
  - Pareto model for top 10%, 5% 1%
  - OLS or robust methods
